* Application requirements: XWidget, Installers Creator Plugin or X-Create plugin installed – required for the formation and monitoring of widgets.The present invention relates generally to digital communications systems, and more particularly to a system and method for detecting problems in digital systems with unknown parameters. With the continued development of digital communications equipment and systems, ever greater numbers of circuit elements are being incorporated into a single chip. In a one-chip system, the number of inputs and outputs of a particular circuit is large. With the present trend toward high-speed processing and complex circuit functions, the numbers of such inputs and outputs are expected to increase further. As these numbers increase, the potential number of defects within the chip also increases. To date, the testing and sorting of these chips has been a laborious and expensive task. Methods for testing and fault isolation within a single integrated circuit have been disclosed in U.S. patent application Ser. No. 07/934,396, filed Aug. 21, 1992, now U.S. Pat. No. 5,388,054, which is incorporated by reference. The disclosure thereof is incorporated herein by reference. That application disclosed a method for detecting and isolating defects which exist within an integrated circuit. Defects in a chip are identified by comparing test vectors to a desired circuit path on the chip. Using this method, a vector is applied to the inputs of a circuit, the outputs of the circuit are measured, and the circuit is compared to the desired circuit path. The failure or defect which caused the difference between the circuit path and the desired circuit path is identified. By isolating such defects, defective components within a chip can be identified and removed, thereby improving the reliability and yield of such chips. This approach, however, requires that the number of inputs and outputs of a circuit be known in order to compare the desired circuit path to the actual circuit path. Further, this approach does not identify a defective circuit within a fault-tolerant circuit which has been designed into the chip. It is possible to utilize testing methods such as those disclosed in U.S. Pat. Nos. 4,864,170 and 5,020,935 to identify defects in a chip which is being tested after the defect is created. These patents disclose a method of testing for defects in a memory device using redundant elements on the chip. A defective memory cell or memory cell array is accessed, and the test pattern is applied to the redundant cell or cells. The outputs of the redundant
